

# Red River Basin Overview

**Considerations for Basin Friendly  
Flood Damage Reduction Alternatives**

# Flood problems are widespread within the Red River Basin

- Throughout the basin, people try to solve their own local flood problems
- These efforts range from small projects on private lands to large public works projects
- Large or small, they can add up to very significant changes in basin hydrology
- It makes a big difference what measures are implemented to solve local flood problems
- It also matters where in the basin the measure is being implemented

# Flood Damage Reduction Measures

- TSAC Technical Paper 11 – Flood Damage Reduction Framework, 2004  
(a product of the MN Flood Damage Reduction Workgroup) (After Adoption of Mediation Agreement)
  - Identified the common flood damage reduction measures.
  - Characterized the impact that these measures are likely to have on basin outflows, which is dependent on their location within the basin.
  - The underlying purpose of TP11 is to guide selection toward measures that address both local and mainstem flood damage reduction goals

# Critical Concept #1 - Timing

The concept of “**Early**”, “**Middle**” and “**Late**” runoff areas within the basin, relative to mainstem flood hydrographs, substantially assists selection of FDR measures for local benefits that take into account downstream impacts.

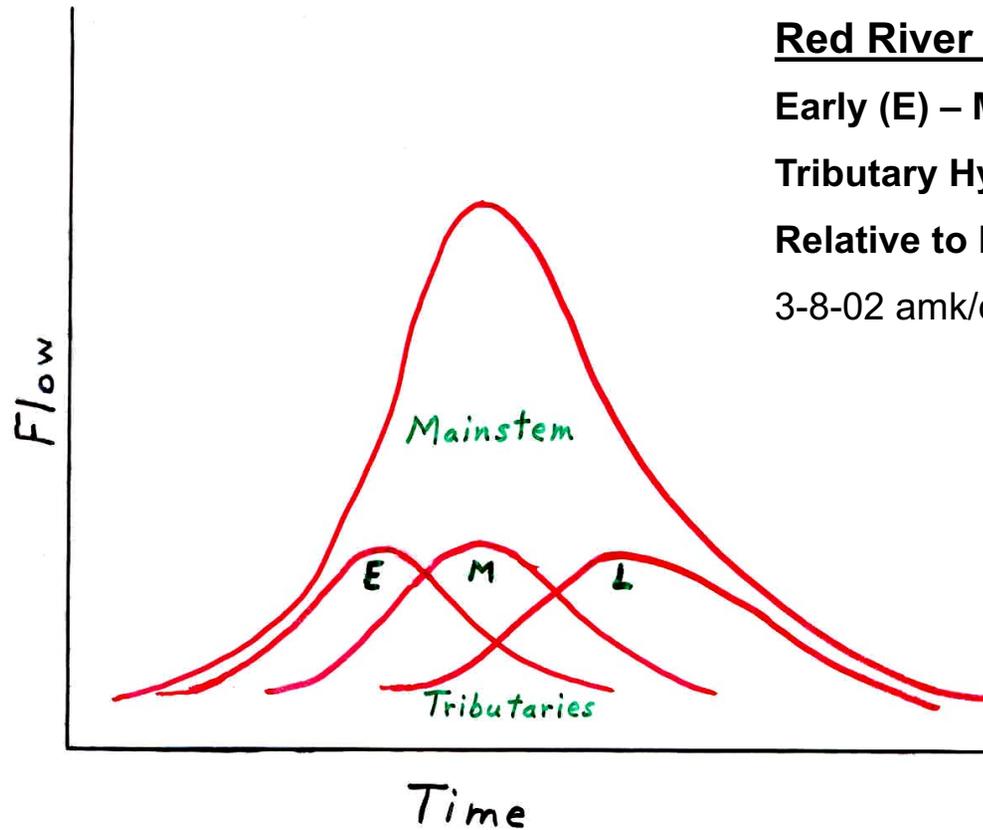

## Red River Basin FDR Strategy

Early (E) – Middle (M) – Late (L)

Tributary Hydrographs

Relative to Mainstem Hydrograph

3-8-02 amk/cia

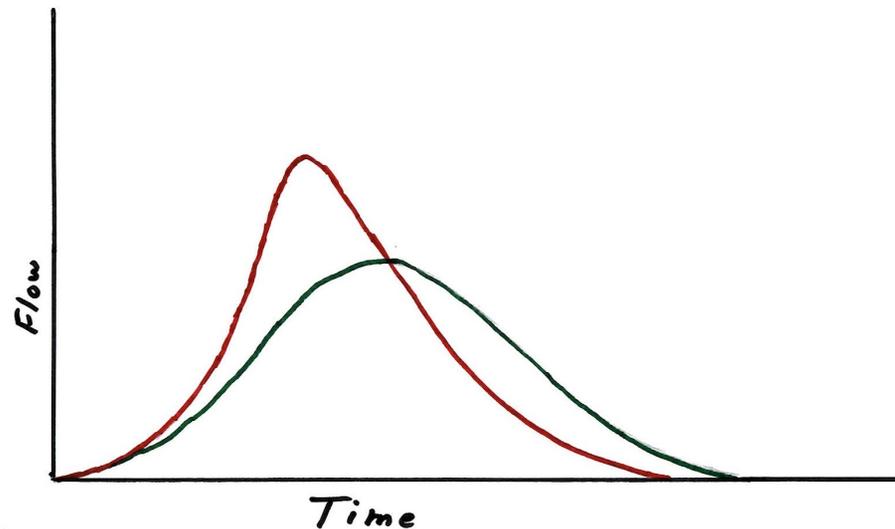

Note: From a Basin perspective, the Red River at Fargo is a tributary. From a Fargo Perspective, Bois de Sioux, Otter Tail, and Wild Rice ND are tributaries.

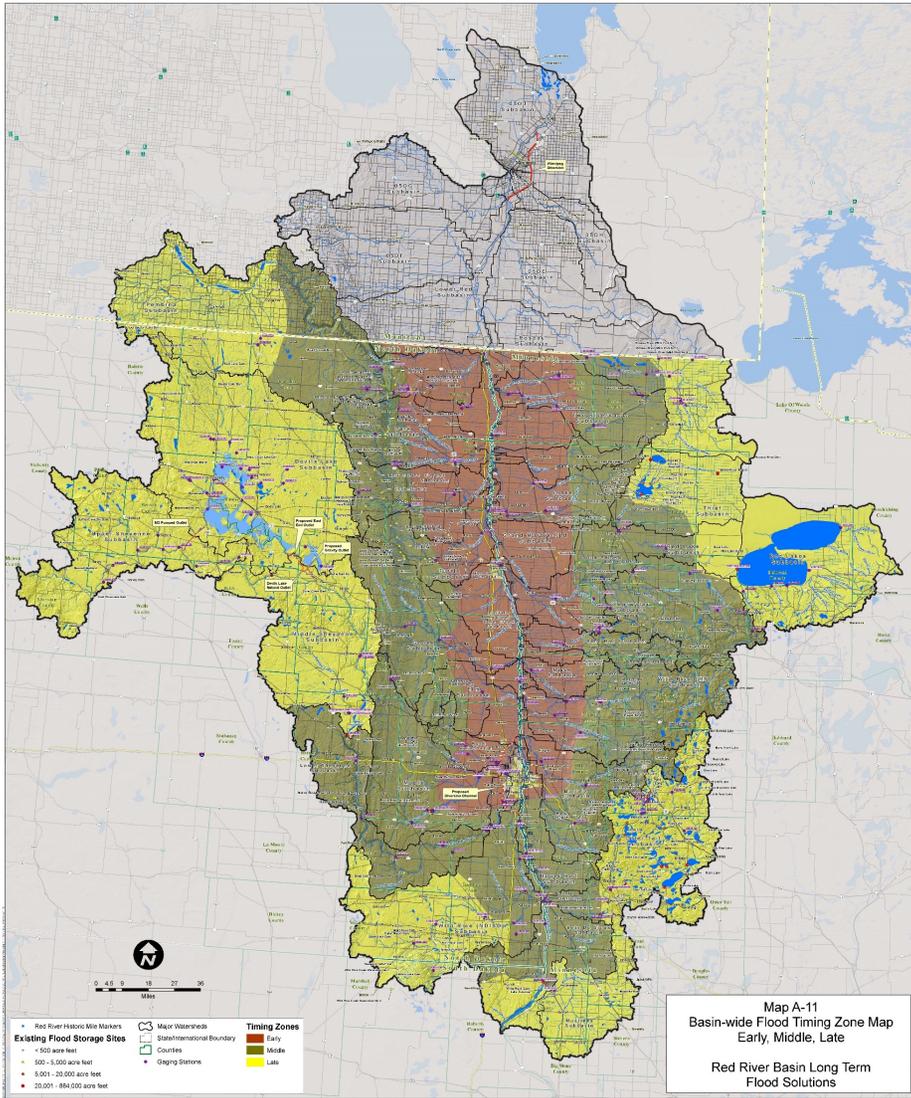

## **Critical Concept #2 – Storage defines the shape of a watershed's hydrograph**

- Within any given watershed, the shape of the hydrograph (its peak and duration) is defined by the amount and location of flood storage within the watershed
- The storage can be artificial (impoundments, etc.) or natural (flood plains, etc.)
- The impacts of an FDR measure can be predicted by how that measure increases or decreases flood storage

# Effect of Flood Storage

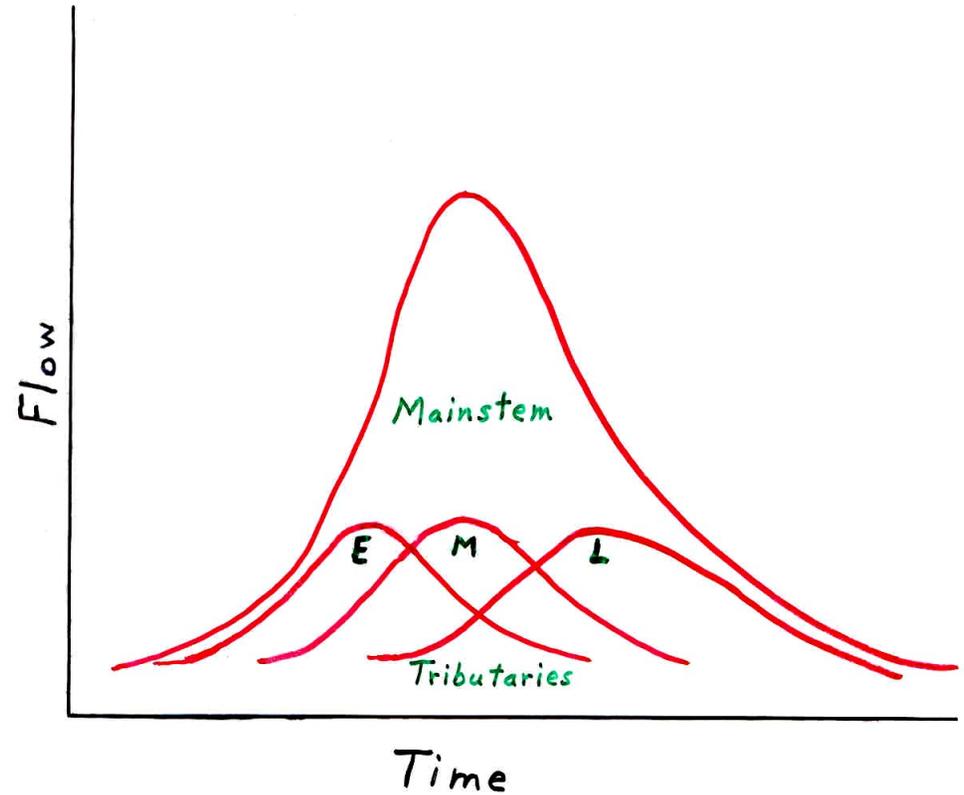

- Reduces and delays peak flow
- Increases the overall duration
- Add storage to go from red to green
- Take away storage to go from green to red

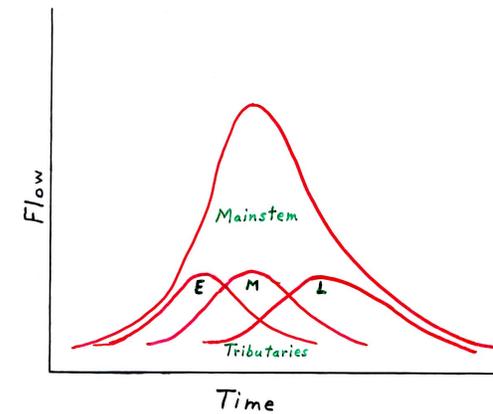

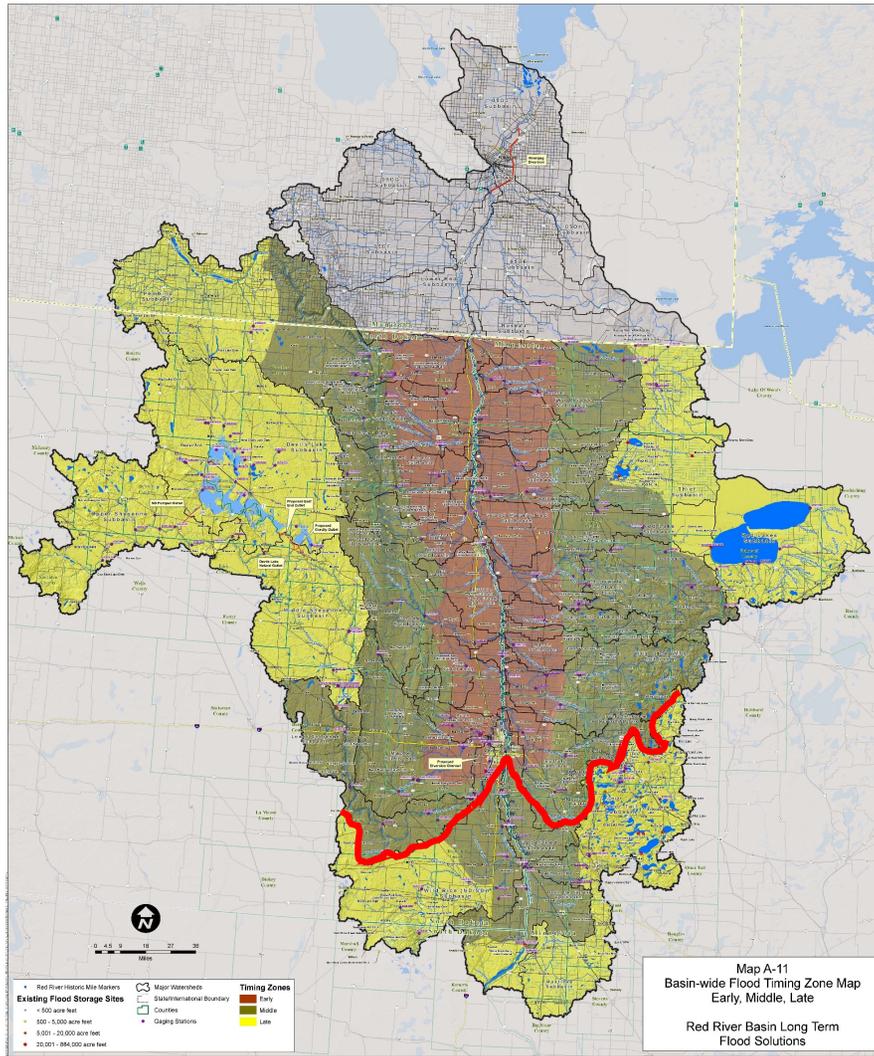

# Basin Timing Map

Timing is affected by storage, travel time, and snowmelt progression

# Red River @ Fargo Drainage Area within the Red River Basin

- The Red River Watershed Upstream of Fargo
  - ~75% within the Basin Late Zone
  - ~25% within the Basin Middle Zone

# Flood Damage Reduction Strategies

1. Reduce Flood Volume
2. Increase Conveyance Capacity
3. Increase Temporary Flood Storage
4. Protection/Avoidance

There are several individual measures within each of the broad strategy categories shown above

# A Basin Approach to Flood Damage Reduction

- All of the aforementioned strategies can be used to provide local FDR benefits
  - Primary consideration should be given to measures that also work toward achieving basin flood damage reduction goals
  - Measures that work against meeting basin flood damage reduction goals should be minimized or avoided, if possible
  - Unavoidable adverse basin impacts should be mitigated

## Downstream Impacts of FDR Measures Applied in Early, Middle, and Late Areas Upstream

| Flood Damage Reduction Measure                                    | Early Upstream Area | Middle Upstream Area | Late Upstream Area |
|---|---------------------|----------------------|--------------------|
| <b>1) Reduce Flood Volume</b>                                     | +                   | ++                   | ++                 |
| a) Wetlands   | +                   | +                    | ++                 |
| b) Cropland BMPs  | +                   | ++                   | ++                 |
| c) Conversion to grassland  | +                   | ++                   | ++                 |
| d) Conversion to forest   | +                   | ++                   | ++                 |
| e) Other beneficial uses of stored water                          | +                   | ++                   | ++                 |
| <b>2) Increase Conveyance Capacity</b>                            | +                   | -                    | --                 |
| a) Channelization   | +                   | -                    | --                 |
| b) Drainage   | +                   | -                    | --                 |
| c) Diversion  | +                   | Variable             | -                  |
| d) Setting back existing levees (to increase conveyance capacity) | +                   | -                    | --                 |
| e) Increasing bridge capacity                                     | +                   | -                    | -                  |
| <b>3) Increase Temporary Flood Storage</b>                        | Variable            | ++                   | +                  |
| a) Gated impoundments   | +                   | ++                   | ++                 |
| b) Ungated impoundments   | -                   | +                    | +                  |
| c) Restored or created wetlands                                   | -                   | +                    | +                  |
| d) Drainage   | -                   | +                    | ++                 |
| e) Culvert sizing   | -                   | +                    | +                  |
| f) Setting back existing levees (to increase floodplain storage)  | +                   | ++                   | +                  |
| g) Overtopping levees   | ++                  | +                    | Variable           |
| <b>4) Protection/Avoidance</b>                                    | Variable            | Variable             | Variable           |
| a) Urban levees   | -                   | -                    | -                  |
| b) Farmstead levees   | -                   | -                    | -                  |
| c) Agricultural levees  | -                   | -                    | -                  |
| d) Evacuation of the floodplain                                   | 0                   | 0                    | 0                  |
| e) Floodproofing  | 0                   | 0                    | 0                  |
| f) Warning and emergency response                                 | 0                   | 0                    | 0                  |

## Downstream Impacts of FDR Measures Applied in Early, Middle, and Late Areas Upstream

| Flood Damage Reduction Measure                                    | Early Upstream Area | Middle Upstream Area | Late Upstream Area |
|---|---------------------|----------------------|--------------------|
| 1) Reduce Flood Volume  | +                   | ++                   | ++                 |
| a) Wetlands   | +                   | +                    | ++                 |
| b) Cropland BMPs  | +                   | ++                   | ++                 |
| c) Conversion to grassland  | +                   | ++                   | ++                 |
| d) Conversion to forest   | +                   | ++                   | ++                 |
| e) Other beneficial uses of stored water                          | +                   | ++                   | ++                 |
| 2) Increase Conveyance Capacity                                   | +                   | -                    | --                 |
| a) Channelization   | +                   | -                    | --                 |
| b) Drainage   | +                   | -                    | --                 |
| c) Diversion  | +                   | Variable             | -                  |
| d) Setting back existing levees (to increase conveyance capacity) | +                   | -                    | --                 |
| e) Increasing bridge capacity                                     | +                   | -                    | -                  |
| 3) Increase Temporary Flood Storage                               | Variable            | ++                   | +                  |
| a) Gated impoundments   | +                   | ++                   | ++                 |
| b) Ungated impoundments   | -                   | +                    | +                  |
| c) Restored or created wetlands                                   | -                   | +                    | +                  |
| d) Drainage   | -                   | +                    | ++                 |
| e) Culvert sizing   | -                   | +                    | +                  |
| f) Setting back existing levees (to increase floodplain storage)  | +                   | ++                   | +                  |
| g) Overtopping levees   | ++                  | +                    | Variable           |
| 4) Protection/Avoidance   | Variable            | Variable             | Variable           |
| a) Urban levees   | -                   | -                    | -                  |
| b) Farmstead levees   | -                   | -                    | -                  |
| c) Agricultural levees  | -                   | -                    | -                  |
| d) Evacuation of the floodplain                                   | 0                   | 0                    | 0                  |
| e) Floodproofing  | 0                   | 0                    | 0                  |
| f) Warning and emergency response                                 | 0                   | 0                    | 0                  |

# Diversion Project components

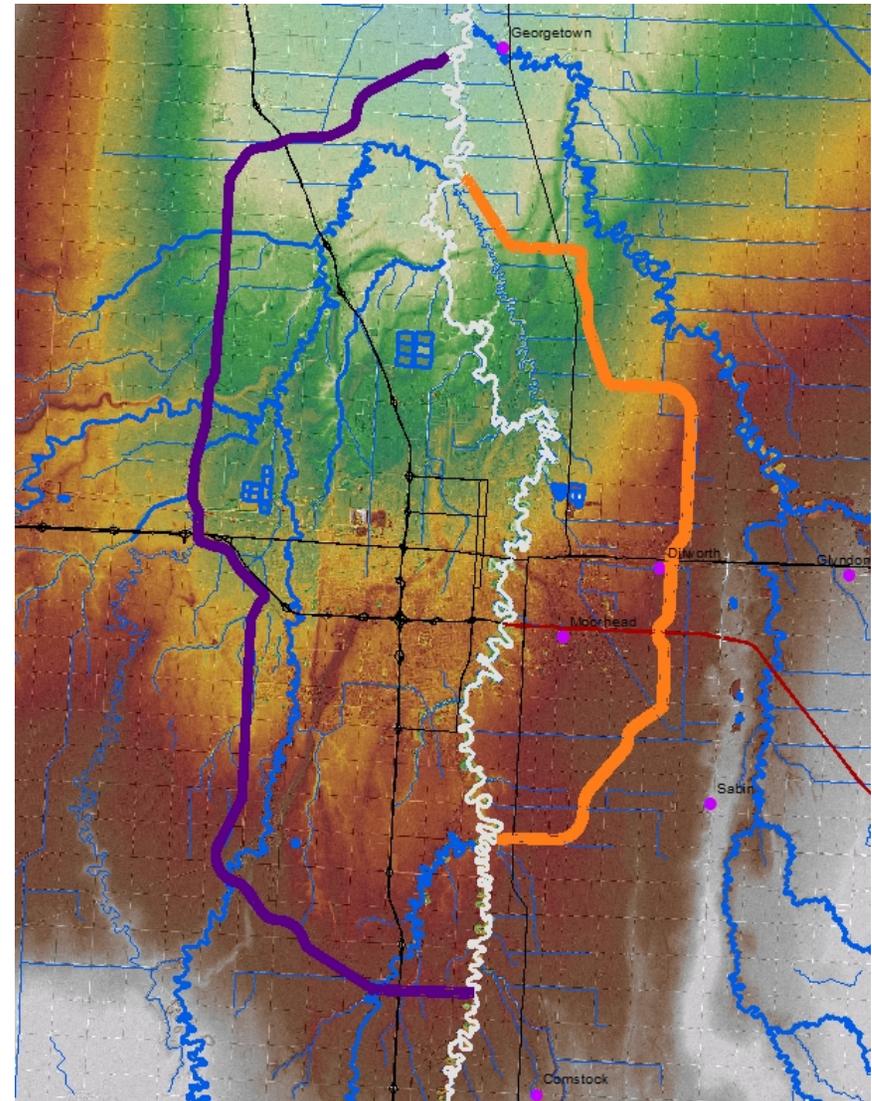

- Diversion Channel
  - Original Stand-Alone Measure and Still the Signature Feature
  - Works Very Well Locally
  - Has Adverse Downstream Impacts
- Levees
  - Traditional/Existing FDR Measure
  - Has Adverse Downstream and Upstream Impacts
- Staging Area
  - Included to Mitigate the Adverse Downstream Impacts of the Diversion and Levees

# Diversion Channel Impacts

- Preliminary analysis considered:
  - Various channel capacities
  - Minnesota and North Dakota Alignments
- North Dakota Alignment has Significantly Greater Downstream Impacts than Minnesota Alignment of the Same Capacity (nearly twice the stage increase)
- Why? - There would have to be a difference in storage effects

# ND & MN Diversion Alignments

- The ND Diversion flows through a low floodplain area thus draining floodplain and also isolating existing floodplain areas, by levees along its alignment, resulting in excessive loss of floodplain storage.
- The MN Diversion flows through higher ground generally not within the floodplain thereby having minimal effect on floodplain storage along the alignment.
- This is the primary reason that downstream impacts were found to be much greater for the ND Diversion.

# Levees

- Levees reduce flood storage by isolating the interior area from the floodplain
- The larger the levee protected area, the greater the loss of floodplain storage

# Staging Area

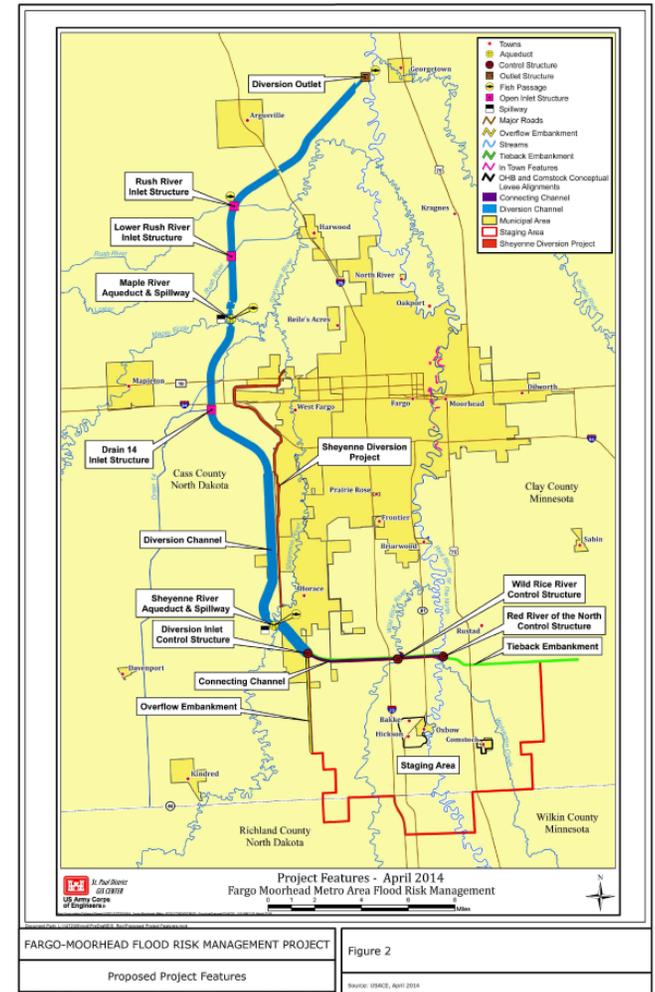

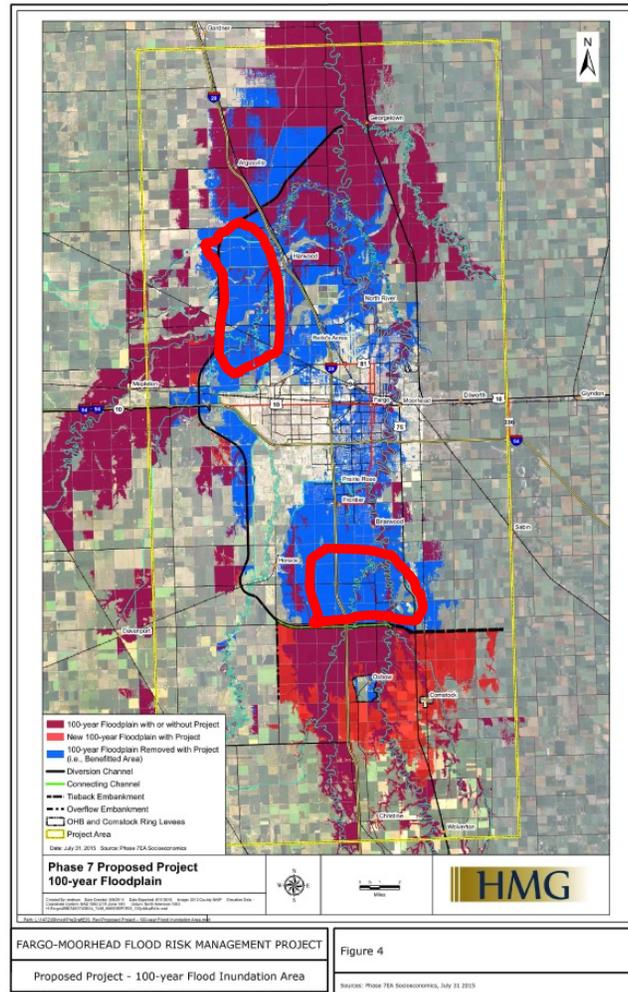

- The Staging Area was Added to the original project primarily To Mitigate the Adverse Downstream Impacts of the Diversion and Levees
- Therefore, the Size of Staging Area is Determined by the Magnitude of those Downstream Impacts which, in turn, is determined by the loss of floodplain storage

# Minimize the Downstream Impacts by Minimizing the Loss of Floodplain Storage

- Diversion
  - Change the Location to the Minnesota Side
  - Move the ND Alignment to East
  - Redesign the Dikework and Structures along the Channel to Restrict Inflows From the Tributaries and Allow Water to Enter the Floodplain Area on the West Side
- Staging Area
  - Move the Dam North (about 4 Miles)
  - The Dam Alignment Should Follow the Edge of the Developed Area as close as practical
- Protected/Benefited Area would be Reduced but that Area is generally Outside of Developed Urban Areas

# Primarily Undeveloped Areas Losing Protection

- Northwest of Fargo
- South of Fargo

# Summary

- The above suggestions for reducing the project impact can be implemented without eliminating any of the basic project features
- The reduced project would still protect the core urban areas
- Reduced benefits would be to primarily undeveloped lands within the existing floodplain
- Additional protection will be added as distributed storage is implemented upstream as part of the basinwide 20% flow reduction strategy
  - Note that 20% flow reduction simply reduces the magnitude of a given frequency flood
  - Changes the peak flow of a 100-yr flood to about that of a 50-yr flood and the peak flow of a 200-yr to about that of a 100-yr flood
